Abstract
The researches were carried out at the use of the precise dilatometer of the firm BAHR 802/801. The device makes possible the registration of changes of measurements of the sample in the function of the temperature. Measurements in the simpler and differential are possible. Heating and cooling is performed in the special device, which realizes the programme temperature, controlled computer.
Changes of dimensions are measured with an inductive sensor. Samples were placed in the quartz-pipe and changes of their length were transferred by quartz-rods. The temperature of tested material was measured by means of the Pt-PtRh thermocouple.
Material on the pistons has a fundamental meaning for the value of the clearances between the cylinder and the piston. Too small clearness between the piston and cylinder on the cold engine cannot be applying, because during the work of an engine it would be able to occur seizing of an engine. From here, also the large resistance on seizing of material of the piston is essential. Investigated composite materials performed based on piston-silumins AK12 and AK18 in which a composite addition was silicon carbide (SiC) and ferric sulphide (FeS).

Keyword: combustion engines, engine pistons, composite alloy, thermal expansion, hysteresis

1. Introduction
In the last period the problems of the development of combustion engines dominate works targeting: the limitation of the emission of harmful components of exhaust gases (the carbon monoxide, hydrocarbons, nitrogen oxides, particulate matters), decreasing of the emission carbon dioxide (what consequently makes for decreases fuel consumptions), increasing durability and dependability work of engines. Essential manner connected with improvement of system-solutions pistons. The most essential influence pistons is reflected in fuel consumption (coefficient of friction and working clearances), the emission of components of harmful exhaust gases (working clearances, coefficient of thermal expansion, the hysteresis of the coefficient of thermal expansion, the heat exchange between combustion chamber and the cooling fluid), noise level and the vibration.

2. The problems of piston-materials for combustion engines
The kind of material on the pistons has crucial role for the correct work of an internal combustion engine. Material on the pistons has a fundamental meaning for the value of the clearances between the cylinder and the piston. Too small clearness between the piston and cylinder on the cold engine cannot be applying, because during the work of an engine it would be able to occur seizing of an engine. From here, also the large resistance on seizing of material of the piston is essential. Investigated composite materials performed based on piston-silumins AK12
and AK18 in which a composite addition was silicon carbide (SiC) and ferric sulphide (FeS). The composite with additives of silicon carbide characterized with a very high resistance on seizing and low coefficient of friction, however the composite with additives of ferric sulphide characterized first of all with the low coefficient of friction and the high resistance on seizing.

3. Test results

The researches were carried out at the use of the precise dilatometer of the firm BAHR 802/801. The device makes possible the registration of changes of measurements of the sample in the function of the temperature. Measurements in the simpler and differential are possible. Heating and cooling is performed in the special device, which realizes the programme temperature, controlled computer. Changes of dimensions are measured with an inductive sensor. Samples were placed in the quartz-pipe and changes of their length were transferred by quartz-rods. The temperature of tested material was measured by means of the Pt-PtRh thermocouple.

7. Conclusions

During the heating and the cooling both increases of measurements, how $\{\text{as}\}$ and diminutions appear.

The hysteresis of the coefficient $\alpha$ occurs during heating and cooling of the pistons, what is reflected by the change of constant dimensions of the pistons during their work in engines.

Under thermal loads, pistons can increase or decrease dimensions, whereat the character of these changes connected with temperature, to which the piston is warmed in the engine.

Within the range low operating temperatures of the pistons the change dispensations cannot appear. Within the range of high operating temperatures of the pistons in engines the change of dimension-pistons appear in most cases.

Established relationship became between temperature of material and with changes dimensions reaching in this material. Within the range low temperatures of the heat treatment, the proper
stability does not receive, even during the very long of the heat treatment.

The receipt of the suitable dimension-stability of the pistons by means of two-grade heat treatment aging in the constant temperature is possible.

The hysteresis of the linear coefficient of thermal expansion \( \alpha \) depends mainly from the kind of crystals of the silicon in the eutectic both in reference to newel alloy, as and standard.

On the value of the hysteresis of the coefficient \( \alpha \) decides the state stress of solid solution.

The double-stage aging of an alloy in temperature 503 K and 483 K decrease considerably the hysteresis

Results of works can be used to decreasing of the clearances between the piston and cylinder, what can contribute to the increasing dependability of the work of the engine, decreasing of the emission of harmful components of exhaust gases, noise level reduction and vibration

In reference to investigated materials the critical temperature, above which appear changes dimensions contains within the range of 523 - 543 K.
